# KeyportARBORIST REPORT and TREE RISK ASSESSMENTArboricultureFor: Save the Davis-Meeker Gary OakConsulting7637 Old Highway 99, Tumwater, WA. 98501

The following arborist report outlines one tree, a large Gary Oak (*Quercus garryana*) white oak tree. This evaluation meets the conditions of a basic limited level 2 tree risk assessment. It will discuss the current condition and recommend future dispositions or treatments for the tree.

Davis Meeker Oak Tree

Disclosure

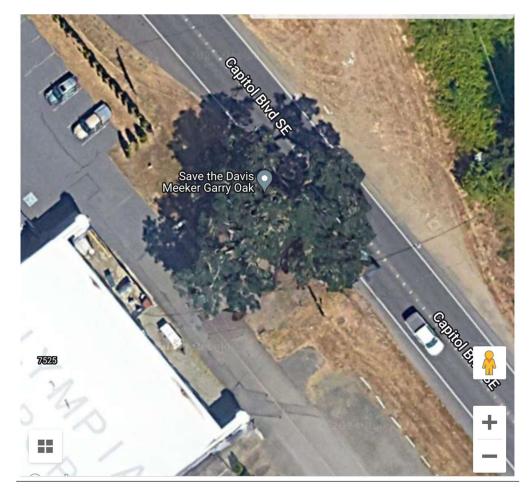

This pro-bono effort is a volunteer opinion by ISA Certified Arborist Paul A. Dubois VI of Keyport Arboriculture Consulting, who is not affiliated with any group, city, contractor, or employer.

The Davis Meeker Gary Oak tree is estimated to be 400 years old. It is a historically significant tree because it is a feature of what once was part of the Oregon Trail—today, living in a growing space next to Old Highway 99 in Tumwater, WA.

Arborists cannot detect every condition that could lead to the structural failure of the tree. Trees are living organisms that fail in ways we do not fully understand. Conditions are often hidden within trees and below the ground. Arborists cannot guarantee that a tree will be healthy or safe under all circumstances or for a specified period. Arborists are specialists who use their training, education, knowledge, and experience to examine trees, recommend measures to enhance the beauty and health of trees, and attempt to reduce the risk of living or working near trees. Tree owners/managers may accept or disregard the arborist's recommendations or seek additional advice and information. The tree's owner/manager makes any decisions regarding treatment or work on the tree. And it is the owner who is responsible for the outcome and consequences. Trees can be managed; they cannot be controlled. To live near trees is to accept some degree of risk. *The only way to eliminate all risk is to eliminate all trees.*  While not a complete biological report, this report is a comprehensive assessment of the Davis-Meeker Gary Oak tree. It describes observations, including general conditions and past failure, and determines the risk, likelihood, and consequences of future failure. All observations are made from the ground, following the ISA Tree Risk Assessment Guidelines and industry best management practices. The risk assessment considers normal circumstances and typical weather conditions in the Puget Sound region. Information from the previous recent Arborist reports was used as part of important data collection for this risk assessment.

## <u>Site</u>

This oak tree lives in compact clay soil and asphalt pavement between a busy highway and an airport service road. Nearby targets that were considered were vehicle and bicycle traffic on the highway. The large airport hangar, the vehicle, bicycle, and pedestrian use of the service roadway, including two parking areas with multiple spaces, and service power lines to the hangar.

### Tools Used:

All available tools were not used due to a lack of access (locked fence) to the trunk and root crown.

Tools onsite included: Mallet, Probe, Binoculars, D-tape, and Rangefinder.

### Notes:

This assessment was not conducted in isolation but relied in part on previous professional Arborist assessments, including written and verbal public statements and pictures, which provided valuable insights into the tree's history and current condition.

The tree genera *Quercus* are among the species known to drop branches unexpectedly in calm conditions and high temperatures. This is called sudden branch drop (SBD) and is not well understood. Currently, it is impossible to predict failure or mitigate risk due to SBD, and it is not included in this report.

On my visit, I observed nesting birds. The nest is in a cavity roughly halfway up one of the main stems, which is a good indicator of the presence of decay.

# **Risk Rating**

The pre-mitigation risk rating per the basic risk assessment is <u>moderate</u>. My observations and previous arborist evaluations have noted decay is present in at least parts of the lower 2/3 of the woody portions of the tree. That decay is the main condition of concern in all the reports. Determining the extent of decay in the upper woody parts is difficult. Before applying the recommended mitigation efforts, I highly recommend an additional aerial/climbing inspection by an arborist familiar with ancient oak trees—specifically White Oaks. One such arborist I recommend, who has over 40 years of experience and is still climbing and working on big old Oaks, is Casey P. Roland of Roland Tree Care in Medford, Oregon. That inspection may change the risk rating and would likely provide information to help choose a mitigation option better. An aerial drone inspection would not be sufficient.

# **Residual Risk and Mitigation**

The following seven actions are recommended and necessary to reduce the current risk assessment rating.

- 1. Introduction of "Arbor" type wood chip mulch (chipped tree parts) onto the existing root zone to cover the entire zone out to the "Dripline" of the tree.
- 2. Aeration and Inoculation of the soil within the root zone with endo/ecto mycorrhizal fungal spores compatible with Oak species.

This is a long-game strategy. Nothing can be done about the decay already in the tree. However, we can improve the tree's ability to defend against pathogens and strengthen the reaction wood growth process against decay. Compartmentalization of Decay in Trees (CODIT). The process of wood chip mulch breaking down not only helps prevent disease microorganisms such as *Phytophthora* and *Armillaria* from living in the soil, but it also becomes usable beneficial nutrients for the tree—bringing the forest to the tree, so to speak.

Fertilizing or introducing new soil can have the opposite effect by giving pathogens more favorable conditions to thrive and reproduce.

3. Remove all the rocks up against or touching the root crown. This will allow a critical and vulnerable area where woody roots join the stem to completely dry out and not hold moisture, making it easier for pathogens to enter.

# Residual Risk and Mitigation continued.

- Selective pruning to remove deadwood greater than 1" in diameter and any limbs in active failure. This action alone will move one part of the risk rating (from Matrix 2) from moderate to low.
- 5. Selective pruning for weight reduction in the lower 2/3 of large scaffolding branches. No cuts should be over 3" in diameter and, when possible, made from parts beneath the larger limbs. No pruning or topping of any "green" limbs in the top 1/3 of the tree crown should be made. No more than 10% to 15% of the healthy "green" limbs in the entire crown should be removed during the pruning operation. This will reduce some weight in the decayed or overextended limbs. All pruning should be done by or under the supervision of an ISA Certified Arborist to ANSI Z-133 requirements and industry best practices.
- 6. Install a support system, such as a dynamic cable system, per ANSI Z-133 Safety Requirements and ISA best practices and standards. This action will reduce load pressure on codominant and decayed limbs, moving the other risk rating (from Matrix 2) from moderate to low and ultimately reducing this tree's overall residual risk rating to low.

\* The recommended aerial inspection can determine the cable system's feasibility, type, and location.

 Restrict pedestrian access beneath the tree and move parking away from the dripline to 1.5 times the tree's height or as far as possible. This will eliminate or reduce the target occupancy rate.

Monitor and inspect the tree at least every two years. Prune as needed. Inspect and adjust the cable system at least every three years. Maintain wood chip mulch in the root zone.

I strongly believe that this special tree can and should be retained. For generations, the benefits this life form has provided humans and our communities are priceless. While constantly evolving, we possess the technology, processes, and science to make informed decisions on how to accomplish best living with and beside old trees in the retrenchment stages of their life span, such as it is. It is easy to cut down and kill it; even 20 or 30 years ago, that may have been the only logical conclusion. Much has changed in our relatively young field of arboriculture, and we have much yet to know.

This report is not intended to disparage or refute the findings of any previous reports or data. Quite the opposite, I could not have completed this report without such work, and I have the utmost respect for anyone who chooses to work on and care for trees. I offer this as a professional opinion and to add to the data already collected and submitted. I am in awe of colleagues in the field of Arboriculture who choose to put themselves into the discussion of this type, as I believe their interests are honorable.

Respectfully Submitted.
